

SL-78. Sympathomimetics

Sympathomimetics are stimulant compounds which mimic the effects of endogenous agonists of the sympathetic nervous system: adrenaline, noradrenaline, dopamine.

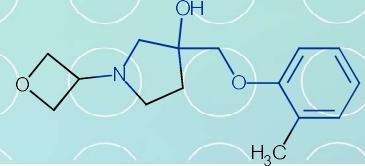

Many sympathomimetic compounds share several common pharmacophoric features including [1,2] an amine group at least two carbons away from an

aromatic group and a hydroxyl group at the beta position to the amine group[1,2].

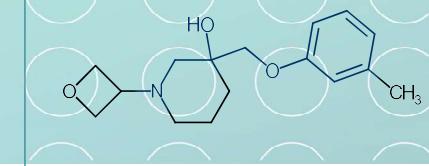

Asinex has developed several analogs of Propranolol - first clinically successful sympathomimetic, containing the characteristic 3-amino-2-hydroxypropanol fragment.
